# NORTH CAROLINA

DEPARTMENT OF ENVIRONMENT, HEALTH, AND NATURAL RESOURCES REGIONS

### PREFACE

This edition of Leading Causes of Mortality describes North Carolina's mortality experience for 1993 and for the latest 5-year period, 1989-93. A companion volume, Detailed Mortality Statistics, provides 1993 counts of deaths classified according to detailed underlying causes of death and the age, race, and sex of decedents.

The tables and maps in this report show selected mortality statistics for counties, Department of Environment, Health, and Natural Resources regions, and the state (see map on preceding page). More than a dozen of North Carolina's leading causes of death are depicted in these tables and maps. In addition, major site-specific cancers and total infant mortality are also tabulated and mapped. Tables 1.A and 1.B on pages 4-3 and 4-4 describe the selected cause-of-death categories in terms of codes from the International Classification of Diseases (Ninth Revision). Altogether, the causes included in this report accounted for 84.5 percent of all North Carolina deaths during 1993.

Based on a survey of users of this volume, it was determined that the multiple conditions present at death data were seldom used. Therefore, that section has been omitted from this edition. Multiple conditions data are, however, available upon special request to the State Center for Health and Environmental Statistics.

IN USING THIS VOLUME PLEASE NOTE THE SECTIONS ON INTERPRETATION OF MORTALITY RATES (Section II) AND CAUTION ABOUT UNSTABLE RATES (Section III).

### I. COMPUTATION OF MORTALITY RATES

In this report, general mortality rates are expressed as resident deaths per 1,000 population, while all cause-specific mortality rates are expressed as resident deaths per 100,000 population. All rates in Tables 1-21 use total population in the denominator, except rates for the sex-specific cancer sites, which use male or female population in the denominator. Population bases for these rates were provided by the Office of State Planning in the Governor's Office. The infant mortality rates of Table 22 and Figure 22 are computed as the number of resident deaths under one year of age per 1,000 resident live births.

Deaths in this report are assigned to place of residence. For deaths of people in long-term institutions (mental, penal, old age, orphan, nursing home, rest home, etc.), the institution is considered the usual residence provided the decedent had resided in the institution at least one year. College students and military personnel are considered residents of the college or military community.

The following definitions apply to the rates of this report:

*Unadjusted Annual Death Rate:* the annual death rate computed as resident deaths per 1,000 or 100,000 population. These rates reflect an area's status according to the observed deaths during the given year.

*Unadjusted 5-Year Death Rate:* the average annual death rate computed as average resident deaths per 1,000 or 100,000 average population. These rates give an area's status with respect to the observed deaths during the 5-year period. These rates are depicted in the Series A maps (e.g., Figures 2.A, 3.A).

Adjusted 5-Year Death Rate: the average annual age-race-sex-adjusted rates computed by the direct method. Also expressed as deaths per 1,000 or 100,000 population, these rates are those that would be expected if the average annual age, race, and sex composition of each county's population were the same as that estimated for the state in 1980. These rates are free of differing effects of age, race, and sex, offering knowledge of an area's status with respect to other factors of mortality during the 5-year period. However, the user should not compare an adjusted death rate to an unadjusted death rate. Also, adjusted rates for different time periods cannot be directly compared unless they were adjusted by the same standard population. The adjusted rates since the 1986-90 time period use the 1980 North Carolina population as the standard. This permits rates to be compared over time beginning with the 1986-90 5-year rate. Adjusted rates are depicted in the Series B maps (e.g., Figures 2.B, 3.B). [Note: For the two sex-specific cancer sites (female breast and prostate), rates are adjusted for age and race, and denominators are sex-specific.]

For the maps, a clustering routine\* from the Statistical Analysis System (SAS) was used to group counties that are "most like each other" with respect to their unadjusted and their adjusted rate. These maps show five levels of death rates, where level one is the lowest rate interval and level five the highest.

A word of caution: Rates for sex-specific cancers (e.g., prostate) use male or female population in the denominator and therefore are not comparable to other rates. Thus, in ranking the causes of death—for example, in ranking the leading cancer sites—one must use the observed <u>numbers</u> of deaths rather than the rates.

<sup>\*</sup>In 1983 the State Center for Health and Environmental Statistics conducted an evaluation of several clustering methods. It was found that the "Average Linkage Method" produced tighter clusters (i.e., clusters with smaller within-cluster variances) than the other methods examined. Consequently, this method is used to cluster county rates in this publication.

### IL INTERPRETATION OF MORTALITY RATES

To assess an area's relative mortality conditions during a 5-year period, both the unadjusted and the adjusted rate can be compared to the corresponding state rates for a particular cause of death. This, of course, should not be done if the area's unadjusted rate had fluctuated widely in recent years. The rate should represent a relatively stable situation. Then, the following alternative interpretations will apply:

Relative Status Of		
Unadjusted Rate	Adjusted Rate	Interpretation of Unadjusted Rate
Low	Low	Low mortality is not due to age, race, and sex factors; other mortality conditions are favorable.
Low	High	Low mortality is due to favorable age, race, and sex factors; other mortality conditions are unfavorable.
High	Low	High mortality is due to unfavorable age, race, and sex factors; other mortality conditions are favorable.
High	High	High mortality is not due to age, race, and sex factors; other mortality conditions are unfavorable.

In using adjusted rates, it is important that the user understand the reason for adjustment. Example: A and B stand for population subgroups, e.g., whites and nonwhites, males and females, etc.

		County			State		
	Population	Deaths	Death Rate*	Population	Deaths	Death Rate*	
Population A	300,000 10,000	1,000 10	333.3 100.0	500,000 800,000	2,500 1,000	500.0 125.0	
Population B Total	310,000	1,010	325.8	1,300,000	3,500	269.2	

<sup>\*</sup>Deaths per 100,000 population.

Compared to the state, county subgroups A and B both have lower rates, but the county as a whole (A and B combined) has a higher rate. This seemingly paradoxical situation results from two factors: different proportions of A and B in the county vs. the state population and wide differences between the rates for A vs. B. In this example, it is true that the county has the higher total rate—BUT ONLY BECAUSE THE POPULATION CONTAINS A HIGH PROPORTION OF SUBGROUP A.

Certainly, it is important for program planners to know that the county has a high rate relative to the state rate; this information is needed in determining manpower, facility, and related needs. But in assessing "risk," the researcher needs to adjust for confounding factors such as age or race. To do this, multiply each population-specific county rate by the corresponding "standard" population, sum these results, and divide by the total "standard." In the above example, using the state population as the standard, the computation is:

$(1000/300,000 \times 500,000) + (10/10,000 \times 800,000)$	
	= 0.001897 or 189.7
1,300,000	per 100,000 population

Thus, as rates specific for A and B imply, the county's rate is lower than the state's rate after adjustment for the factor represented by A and B.

### Caution!

In assessing the relative mortality conditions of a county, be particularly aware of rates based on small numbers of deaths since, in such cases, random fluctuation in the rate may render rate comparisons risky. The reader should read very carefully the next section entitled "Caution About Unstable Rates."

### III. CAUTION ABOUT UNSTABLE RATES

Any rate with a small number of events (deaths) in the numerator will have substantial random variability over time, or a large standard error. A useful rule of thumb is that any rate based on fewer than 20 events in the numerator may involve serious random error and should be used very cautiously in making comparisons or assessing trends. Many of the rates in this volume do have numerators smaller than 20.

In addition to the problem of a large standard error in death rates due to a small numerator, the age-race-sex-adjusted rates in this volume may be unstable because of small age-race-sex population groups. One death out of an estimated population of five, for example, would produce a death rate of 20,000 per 100,000 population. If this rate were applied to the appropriate age-race-sex group of the standard population, a very large number of expected deaths would result and the adjusted rate would be extremely high. On the other hand, zero deaths in several population groups may result in a very low age-race-sex-adjusted rate. Counties with a very small nonwhite population, predominantly in western North Carolina, are particularly subject to extreme age-race-sex-adjusted rates (high or low) due to small age-race-sex-specific population groups. Unusually high or low rates in this volume should, therefore, be interpreted with caution.

IV. TABLES AND FIGURES: MORTALITY STATISTICS FOR 1989-93
